

3 tips for bigger arms. 💪

Channel: Brandon Carter · Published: Jul 07, 2026 · Watch: <https://www.youtube.com/shorts/w7t8UqxnkvU> Source: full transcript

Executive Summary

Brandon Carter outlines three essentials for arm growth: heavy compound lifts, wrist-supination curl variations to fully recruit the bicep, and hitting at least 1 gram of protein per pound of bodyweight daily.

Contents

- 🏋️ Tip 1: Prioritize Compound Movements
- 🔄 Tip 2: Incorporate Wrist-Twist Movements
- 🍖 Tip 3: Eat Enough Protein

Tip 1: Prioritize Compound Movements 0:00

- Focus first on heavy compound lifts rather than isolation work
 - Exercises mentioned: bench press, bent-over rows, pull-ups, overhead press
- Key observation: "You never see somebody who can bench a lot with little arms"
 - Heavy compound pressing and pulling forces the arms to grow as a byproduct of moving serious weight

Tip 2: Incorporate Wrist-Twist Movements 0:22

- The bicep has two functions: flexion AND supination (rotating the wrist)
 - Twisting the wrist alone moves the bicep even without a conscious flex — demonstrating it handles supination
 - Most standard curls only train flexion, leaving the supination function undertrained
- Recommended exercise: rope curls with a flare-out at the top
 - Use a rope attachment on a cable, curl up, then bring hands out to the sides at the top
 - Carter describes the arm path as making "the shape of a uterus" to cue the outward supination motion
- This twist at the top fully recruits the bicep through its complete range of function

Tip 3: Eat Enough Protein 0:22

- **Target: at least 1 gram of protein per pound of bodyweight per day**
- Training alone is not enough — diet is the limiting factor
 - Direct quote: "I don't care how much you lift. If your diet is not on point, you will not see results."

- No specific food sources mentioned; the emphasis is purely on hitting the minimum protein threshold consistently
